

A data center’s heat could warm a 10-hectare year-round farm and 500 homes

Heat from the data center feeds a community-owned utility. Cooling never depends on it. Lansing could say yes, with conditions.

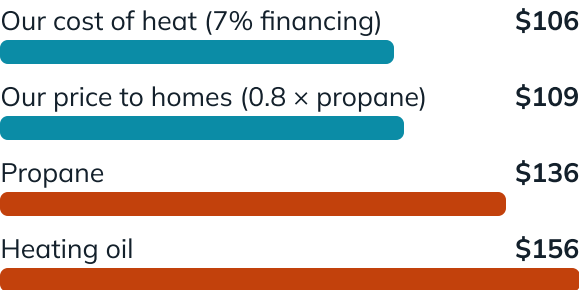

Three rings, built in phases

The rings

- Phase 1: On-site campus**
37 GWh/yr · 45 °C
- Phase 2: Corridor homes**
14 GWh/yr · 20 °C · 500 homes
- Phase 3: Town center (fails the cost test today)**
4 GWh/yr · 65 °C

Cost of heat, \$ per MWh

The cost is an average: the farm campus costs \$41, the homes \$286. The benefit agreement covers the gap.

Safeguard: dry coolers keep 100% heat-rejection backup; 0 unmet hours modelled.

The ask

Make a binding Community Benefit and Heat Supply Agreement (about 1.7% of the data-center build) a condition of any approval, plus a proposed \$150k a year for computer science in Lansing's public schools. About 126 jobs and 5,500 t of local food a year (estimates). Code and model: <https://github.com/harshagarwalnyu/Data-Center-Heat-Reuse>
